Introduction to Programming with R

Dries Debeer & Benjamin Becker

31. September and 01. October 2021

Zurich R Courses

Introduction

Who are we?

Dries Debeer

Senior Researcher at itec (imec Research Group at KU Leuven)

scDIFtest, permimp, eatATA, mstDIF

dries.debeer@kuleuven.be

Benjamin Becker

Researcher at IQB (Statistics Department)

eatGADS, eatDB, eatATA, pisaRT

b.becker@iqb.hu-berlin.de

Introduction

Introduction

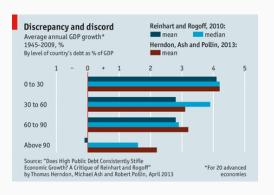

Who are you?

- 1. Institution and Status
- 2. Previous knowledge and experience
 - with R
 - with other statistic software
 - with other programming languages
- 3. Specific interest/motivation for this workshop?

- Being more efficient in your research
 - Save time and nerves
 - Avoid errors and bugs
 - High transfer effect to all projects (with data analyses)
- Successful collaborations (with your future self?)
- Code as part of paper submissions

Two of your worst enemies

- Past Self
 - Is the biggest mess in existence
 - Did not document anything
 - Uses a completely different style of writing code than yourself
 - Is the worst collaborator (does not reply to e-mails)
- Future Self
 - Has the memory of a goldfish
 - Will have zero understanding for your current brilliance

Concept of Technical Debt

- We write (messy) code for data cleaning/analyses
- We decide on data sets/models/graphs/tables/...
- We try to publish it, get a major revision
- We need to rerun some analyses
- Modifying/extending our code is more difficult than it should be

Trade-off

Being fast vs. writing (or refactoring) perfect code

But also

• Write better R code

7

goal

Goal of this workshop

An introduction to R as a Programming language

- Better practical R skills
- Better theoretical understanding of R (and programming)
- Different framing: R as a programming language

Agenda

Day 1

- Basic elements & data types of the R language
- Flow & conditional programming
- Loops & iteration
- Writing & using functions (part I)

Day 1

- Writing & using functions (part II)
- Programming tools in R: run time analysis, debugging, exception handling
- Good programming practices

RStudio setup

RStudio setup

- 1. Copy the course content from the usb-stick to a directory on your machine
- 2. Open RStudio
- 3. Choose File < New Project ...
- 4. Choose Existing Directory
- Browse to the directory on your machine where you copied the course content and select the "Intro-R-programming" folder as the Project working directory
- 6. Click Open in new session
- 7. Click Create Project

RStudio setup - optional

- 1. Choose Tools < Global options
- 2. Under General
 - DON'T Restore .RData into workspace at startup
 - NEVER Save workspace to .Rdata on exit:
- 3. Further personalize RStudio

Agenda

Day 1

- Basic elements & data types
- Flow and conditional programming
- Loops and iteration

Day 2

- Functions
- Good programming practices
- Programming tools in R: run time analysis, debugging, exception handling

Basic elements & data types

"To understand computations in R, two slogans are helpful: Everything that exists is an object. Everything that happens is a function call."

— John Chambers

Basic elements & data types

- What are objects?
- Atomic vectors
- Vector structures
- Subsetting
- Replacement

What are objects?

- Data-structures that can be used in computations
- Collections of data of all kinds that are dynamically created and manipulated
- ullet Can be very small, or very big. o Everything in R is an object
- Elementary data structures can be combined in more complex data structures
- Creating new types of complex objects is part of programming in R (S3, S4)

Atomic Vectors - Basic Building Blocks

Basic object types	
logical	TRUE, FALSE, NA
integer	1L, 142, -5,, NA
double	1.0, 1.25784, pi,, NA
	NaN, -Inf, Inf
character	"1", "Some other string",, NA

mulitple values in one object \rightarrow length() starting from 0

Atomic Vectors - Basic Building Blocks

Elements of the same type can be combined into an atomic vector using c.

All elements are of the same type!

Atomic Vectors - Basic Building Blocks

An important object type with special behavior is NULL. It is an empty object that can be interpreted as *nothing*. It's length is 0.

```
length(NULL)
# [1] 0
```

NULL is mostly used as a default argument in functions, in order to create some default behavior.

Useful Functions

?seq Creates a vector with a sequence of numerical values.

```
seq(0, 10, by = 2)
```

[1] 0 2 4 6 8 10

```
seq(0, 1, length.out = 11)
```

```
[1] 0.0 0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9 1.0
```

```
seq_along(letters)
```

```
[1] 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 [26] 26
```

```
seq_len(10)
```

Useful Functions

```
?rep Creates a new vector by repeating the elements of a vector.
rep(1:3, each = 2)
[1] 1 1 2 2 3 3
rep(1:3, times = 2)
[1] 1 2 3 1 2 3
rep(c("a", "b", "c"), times = 2)
[1] "a" "b" "c" "a" "b" "c"
rep(c("this", "may", "be", "useful", "!"), 1:5)
```

[1] "this" "may" "may" "be" "be" "be" "useful" "useful" [9]

?paste Creates a character vector by pasting multiple vectors together.

```
paste("one", "big", "string", sep = " ")
```

[1] "one big string"

[1]

```
paste0("word", seq(1,10))
```

collapse = $"_{-}"$)

```
paste(c("ONE", "TWO"), seq(1, 3), sep = " || ",
```

"word₁"" word₂"" word₃"" word₄"" word₅"" word₆"" word₇" [8]" word₈"" word

```
[1] "ONE ||1_TWO||2_ONE||3"
```

Useful Functions

?unique Creates a vector with the unique values of a vector.

```
unique(c("b", "a", "a", "b"))
```

?sort Creates a sorted version a Vector.

```
sort(c("b", "a", NA, "a", "b"), na.last = TRUE)
```

```
sort(c(4, 2, 6, 1, 3, 5), decreasing = TRUE)
```

Coercion/Conversion

Automatic conversion:

 $\mathsf{NULL} \to \mathsf{logical} \to \mathsf{integer} \to \mathsf{double} \to \mathsf{character}$

```
1 + TRUE
# [1] 2
```

Explicit conversion:

```
as."type"() as.vector(, mode = "type")
```

```
as.logical(0:5)
# [1] FALSE TRUE TRUE TRUE TRUE
```

atomic vectors - check type

```
Check type using: is. "type"()
is.null(NULL)
# [1] TRUE
Check type using: typeof()
typeof(TRUE + FALSE)
# [1] "integer"
```

Assignment

In order to compute with objects efficiently, names can be assigned to the objects using the assignment operator <- (or =)

```
my_object <- TRUE
my_object
# [1] TRUE</pre>
```

- The objects (with references) that are available to a user can be seen in the global environment using 1s().
- R overrides previous assignments without a message. Removed objects (rm(objectName)) cannot be restored.
- \rightarrow May the source code be with you!

Attributes can be attached to objects. An attribute:

- has a name
- is itself also an object
- attributes are easily lost in computations. (One of the reasons to use OOP with classes and methods.)

There are several attributes with a specific use: "names", "dim", "class", "levels"

- "names" is a character vector that contains the names of elements of the vector/object. Names can be printed and set using names(object) <- .
- "dim" is an integer vector that specifies how we should interpret the vector (i.e., as a matrix, as an array). The dimensions of a vector can be printed and set using dim(object) <- .
 - ightarrow a matrix or array is a vector with a "dim" attribute.

- "class" is a character vector that contains class names.
 Classes can be printed and set using class(object) <- .
 See Object Oriented Programming (\$3)
- "levels" is a character vector that contains the names levels of a factor. Levels can be printed and set using levels(factor) <- .

A factor in R is actually an integer vector with

- a "class" attribute set to "factor"
- a "levels" attribute set to the level-labels that correspond to the integer values from 1 to the highest integer value in the integer vector.

More Basic Object Types

More basic object types	
complex	1 + 2.31i, NA
raw	as.raw(2), charToRaw("a")
expression	expression(1+1, sum(a, b))
language	a function call, quote(1 + y)
closure	function(x) x - 1, mean
builtin	sum, c
special	for, return
environment	an environment
symbol	quote(x)

Vector Structures

More basic object types	
list	list(), as.list(),
matrix	a vector with "dim" argument: two dimensions
	matrix(), as.matrix()
	matrix algebra
array	a vector with with "dim" argument
data.frame	a list with vectors of equal length
	<pre>data.frame(), as.data.frame()</pre>

List

A list is a "vector" that can contain any type of elements

- ullet the types of elements can differ \leftrightarrow atomic vectors
- ullet possible elements including lists o recursive
- can have attributes

Matrix & Array

A matrix or an array is a vector with a "dim"-attribute

- mostly usefull for numeric vectors (integer and double)
- matrix algebra! t(matrix), %*%, aperm(array), ...
- matrix has two dimensions, array has n dimensions
- cbind(vector1, vector2)
- rbind(vector1, vector2)
- matrix(vector, ncol = 4, nrow = 2)
- array(vector), dim = c())

Data.frame

A data frame is a list of (named) vectors of equal length.

- has dimensions (but not a "dim"-attribute)
- the columns are the vectors
- the vectors can be lists (using I()).
- a data.frame has row names (but ignore these)

A subset of elements from a vector can be accessed using object [selection], where selection is:

- a logical vector with the same length of the original vector (TRUE: select; FALSE: don't select)
- an integer vector indicating the indexes of the elements to select (or exclude)
- a character vector with the names of the elements to select

Using a logical vector:

- the logical vector should have the same length as the object. If shorter, the logical is repeated; if longer, NAs are added if TRUE. → always use the same length!
- handy when you want to select based on a condition related to the object values

Using a logical vector:

```
my_object <- c(a = 1, b = 5, c = 3, d = 8)
my_object[my_object > 4]

# b d
# 5 8
```

Using an integer vector:

- the integer vector can have any length (repeated indices are repeatedly selected)
- positive values mean select, negative values mean drop
- positive and negative values cannot be combined
- for integers higher than the number of elements in the vector,
 NAs are added
- using which() a logical vector is transformed in an integer vector with the indices of the elements that were TRUE
- double elements are truncated towards zero (using as.integer())

Using an **integer** vector:

```
my_object <- c(a = 1, b = 5, c = 3, d = 8)
my_object[c(1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2)]
# a b a b a b a b a b a b
# 1 5 1 5 1 5 1 5 1 5 1 5</pre>
```

Using a character vector:

- the strings that match with the names of the elements in the vector are returned
- the character vector can have any length (repeated names are repeatedly selected)
- only selection is possible (dropping is not)
- strings that are not matched with names return NA

Using a **character** vector:

```
my_object <- c(a = 1, b = 5, c = 3, d = 8)
my_object[c("a", "b")]
# a b
# 1 5</pre>
```

A **sinlge** element from a vector can be accessed using object[[selection]], where selection is:

- an integer value indicating the index of the element to select
- a character vector with the name of the element to select

```
my_object <- c(a = 1, b = 5, c = 3, c2 = 8)
my_object[[2]]
# [1] 5</pre>
```

Subsetting - Matrix & Arrays

Because arrays and matrices are atomic vectors (with a "dim" argument), the rules for atomic vectors apply.

Subsetting - Matrix & Arrays

In addition, selection is possible per dimension:

- separated by a comma [,]
- selection via character (match row or column names), integer (row and column number) or logical vectors
- the first vector selects the rows, the second the columns (and so on)
- dimensions are dropped, unless drop = FALSE

Subsetting - Matrix & Arrays

Finally, the selection element can also be a matrix (with one column per dimension). Each row in the matrix selects one value.

Subsetting - **Lists**

For lists, the rules are similar as for atomic vectors.

- list[selection] gives a list (i.e., a subset of the original list)
- list[[selection]] gives the element (which can be a list)
- list[["element_name"]] is the same as list\$element_name

```
my_list<- list(a = 1, b = 5, c = 3, d = 8)
is.list(my_list["a"])
# [1] TRUE
is.list(my_list[["a"]])
# [1] FALSE</pre>
```

Subsetting - data.frames

Because data.frames are lists, the rules for lists apply.

Subsetting - data.frames

In addition, the selection rules for matrices can be used:

- selection per row and column (note the drop argument)
- selection via a matrix with two columns

Element Replacement

A subset of elements from a vector or vector structure can be replaced using object[selection] <- new_values:

- the modifications are done in place
- the structure and class of the object stay unchanged
- the length of the new values should correspond with the length of the selection (the number of elements to replace should be a multiple of the number of new values)
- only for lists, the replacement can be NULL (which removes the element from the list)

Element Replacement

"To understand computations in R, two slogans are helpful: Everything that exists is an object. Everything that happens is a function call."

— John Chambers

Function Calls

- Computing in R happens through function calls. A function is applied to one or more objects, and returns an object after the computation.
- The typical use is: function_name(object1, argument_name = object2)
- Computations that seem not to be done using functions are actually also functions. Check `<-`(a, 5) or `>`(5, 2)
- most functions that seem not to return an object, return it invisibly. Check (a <- 5).

"Write code for humans, not for machines!" $\,$

Code Style

Invest time in writing readable R-code.

- It will make collaborations easier
- It will make debugging easier
- It will help make your analyses reproducible

There is a complete *tidyverse* style-guide https://style.tidyverse.org/.

Go easy on your eyes

- with spaces before and after: + / * = <- < == >
- always use <- for assignments
- only use = in function calls
- use indentation (largely automatic in RStudio)
- CamelCaseNames vs snake_case_names
- be consistent!
- wrap long lines at column 70-80 (Rstudio)

White spaces

```
new_var=(var1*var2/2)-5/(var3+var4)

# versus

new_var <- (var1 * var2 / 2) - 5 / (var3 + var4)</pre>
```

Indentation

```
for(name in names){formula=as.formula(paste0("y~.-",name))
fit<-lm(formula, data=my_data)</pre>
coefs[["name"]]=coef(fit)
print(name)
print(summary(fit))}
 versus
for(name in names){
  formula <- as.formula(paste0("y~.-", name))</pre>
  fit <- lm(formula, data = my_data)</pre>
  coefs[["name"]] <- coef(fit)</pre>
  print(name)
  print(summary(fit))
```

Wrap long lines

```
final_results <- data.frame(first_variable =</pre>
sgrt(results$mean_squared_error), second_variable =
paste0(results$condition, results$class, sep = ":"),
third variable = results$bias)
# versus
final_results <- data.frame(</pre>
  first_variable = sqrt(results$mean_squared_error),
  second_variable = paste0(results$condition,
                            results$class, sep = ":"),
  third_variable = results$bias)
```

Go easy on your mind

- use meaningful names: "self-explainable"
- always write the formal arguments in function calls (except the first)
- benefit from autocompletion (<tab>) => embrace longer names
- use TRUE and FALSE not T and F
- comment, comment, comment
 - not what (should be clear from the code)
 - but why
 - explain the reasoning, not the code

Use meaningful names

```
V <- myFun(m1_B)
# versus

RMSE_age_gender <- get_RMSE(lm_age_gender)</pre>
```

Use verbs for functions and nouns for objects.

Write formal arguments

Benefit from auto completion using tab

Comment, comment

```
## Start every Rscript with a comment that explains
   what the code in the script does, why it does
##
   this, and to which project it belongs.
##
   Your future self will be very thankful!
##
## Mention which packages you are using in this Rscript.
## Use sections to separate chunks -----
## Maybe even subsections =================
## Recode variables so that missings are coded as "NA"
dat[dat %in% c(99, 999)] <- NA # missings coded 99 or 999
```

Keep your code slim

Try to limit your package-dependencies.

Only load library() the packages that you absolutely need. If you are only using dplyr, it does not make sense to load the complete tidyverse.

Controversial: when possible, use the :: operator (and consider not loading the package). chape::<function>

- explicit dependencies
- less name conflicts

Never Attach

Forget about attach()!

Don't use it, unless you completely understand what happens (see ?attach).

Use with(data.frame, expression) instead.

Testing R code

Writing code is error prone. Incorporate tests and checks in your workflow. For instance, when you do data manipulations like a complex restructuring of the data, or a complex recoding of multiple variable, write some code that allows you the check whether the obtained results are what you want them to be.

- minimal examples
- write test and checks
- helpful packages: testthat, RUnit, testit, ...

"Every project should get an RStudio Project!"

Don't use setwd("pathtomylocal_folder")

Issues when:

- folders names are changed
- folders are moved
- a shared drive is used
- you ZIP and send the folder

Don't save workspace to .RData.

- Tools < Global Options < Workspace < Save workspace
- Save the code instead!
- saveRDS() and readRDS() for objects that require long computations

Don't use rm(list = ls()) at the start of an Rscript.

- Start clean, everytime.
- Keep it clean. No outside code, no outside computing.
- Regularly completely clean the workspace (or restart the session).

```
.rs.restartR()
```

Keep it clean

- one folder per project!
- work on different projects in different RStudio instances!
- each with own R console, working directory, ...

Organize your project folder

- R-folder with R scripts
- Data-folder with data
- split long scripts in meaningful chunks
- use relative paths (alternative: here-package)

```
# read data
this_data <- read.csv("Data\the-correct-file.csv")

# source Rscript
source("R\0_first-script-to-source.R")</pre>
```

Use keyboard shortcuts

- Can make working in RStudio more efficient
- Completely tunable: Tools < Modify Keyboard Shortcuts...
- Useful shortcuts (defaults):
 - jump to editor: ctrl + 1
 - jump to console: ctrl + 2
 - jump to ...: ctrl + 3-9
 - jump to next tab: ctrl + tab
 - jump to previous tab: ctrl + shift + tab

More useful shortcuts (defaults):

- run selection/selected line: ctrl + enter
- save current file: ctrl + s
- close current file: ctrl + w
- restart R: ctrl + shift + F10
- Show help (for function at cursor) F1
- Show source code (for function at cursor) F2

More on this HERE.

Exercises

Flow & conditional programming

Flow & conditional programming

R has specific tools (functions) that help organize the flow of computations.

You can make computations conditional on other objects ("conditional computation") The most commonly used tools are:

- if (+ else)
- ifelse
- switch

if statements have the basic form

```
if(test){
  some_computations
}
```

- test should be either TRUE or FALSE (or code that results in one of both).
- If test == TRUE, than some_computations is executed, if test == FALSE, than not.
- Important: test should have length 1. If not, only the first element is considered.

else can be added, but it is optional

```
if(test){
   some_computations
} else if (test_2){
   other_computations
} else {
   more_computations
}
```

Typical test functions

Vectorized

- ==, !=, >, >=, ...
- is.na()
- &, |

Not vectorized

- identical()
- all.equal()
- &&, | |
- any(), all()
- is.character(), is.data.frame(), ...

The test should have length 1!

```
# only the first element is evaluated
age <- c(8, 17, 39, 55)
if (age >= 18) {
    "can vote"
} else {
        "too young"
}
# [1] "too young"
```

Typical uses

```
if(any(is.na(x))){
  stop("computation impossible due to NA values")
if(!is.integer(vector)){
  warning("'vector' is automatically converted to interger.
          This may affect the results")
  vector <- as.integer(vector)</pre>
if(is.null(default_argument)){
  <default computations>
} else if (default_argument == specific value) {
  . . .
```

Programming advice

- if is almost always used inside of functions or loops
- If possible, avoid using else
- Use meaningful initialisation, early return(), stop(), etc. instead

Abbreviation for if(!test) and stop():

```
mean2 <- function(x, na.rm = FALSE) {
   stopifnot(is.numeric(x))
   sum(x)/length(x)
}
mean2("a")

# Error in mean2("a"): is.numeric(x) is not TRUE</pre>
```

A vectorized version is ifelse().

Go-to tool for conditional recoding

Conditional Computation - Vectorization

Pure vectorization can bring you a long way. But it is certainly less readable

```
age <- c(8, 17, 39, 55)
c("too young", "can vote")[1 + (age >= 18)]
# [1] "too young" "too young" "can vote" "can vote"
```

Conditional Computation - switch

switch() is often a more elegant solution than using else if ()
multiple times.

```
method <- "method 5"
switch (method,
       "method 1" = <computations>,
       "method 2" = <computations>,
       "method 3" = <computations>,
       "method 4" = <computations>,
       "method 5" = <computations>,
       "method 6" = <computations>,
       "method 7" = <computations>,
       "method 8" = <computations>,
       stop("Not an existing method"))
```

Loops & Iteration

Loops & iteration

R has specific tools (functions) that help organize the flow of computations.

You can repeat a similar computation multiple times typically with changing options ("iteration"). The most commonly used tools are:

- loops (repeat, while, for)
- functionals (apply family)

Loops & Iteration - for

for statements have the basic form

```
for (element in vector) {
  computation
}
```

For each element in the vector, the computation is executed. Often, the computation depends on the element in that iteration.

Loops & Iteration - for

```
for (index in 1:3){
  cat(" computation -")
#
  computation - computation - computation -
for (name in c("Alice", "Bob", "Casey")){
  if(name == "Bob") cat(" This was Bob -")
  else cat(" Not Bob -")
   Not Bob - This was Bob - Not Bob -
```

Loops & Iteration - for

```
matrix <- matrix(NA, nrow = 2, ncol = 3)</pre>
for (rowNr in 1:2){
 for (colNr in 1:3){
   matrix[rowNr, colNr] <- rowNr * 10 + colNr</pre>
matrix
      [,1] [,2] [,3]
# [1,] 11 12 13
# [2,] 21 22 23
```

Loops & Iteration - while

while statements have the basic form

```
while (condition){
  computation
}
```

As long as the condition is TRUE, the computation is executed. Often, the computation depends on something that is related to the condition.

Loops & Iteration - while

```
max_abs <- 0
while (max_abs <= 3){
  cat("|")
  values <- rnorm(20)
  max_abs <- max(abs(values))
}
max_abs</pre>
```

Loops & Iteration - repeat

repeat statements have the basic form

```
repeat {
  computation
}
```

Without a break the computation is repeated infinite times

Loops & Iteration - next break

- next starts next iteration
- break ends iteration (of the innermost loop)

```
index <- 0
repeat {
  index <- index + 1
  if (index \frac{1}{n} c(3, 5)) next
  if (index > 6) break
  print(index)
# [1] 1
# [1] 2
# [1] 4
# [1] 6
```

Iteration - Good practice

Programming advice

Use seq(), seq_len(), or seq_along().

```
x <- numeric()
for (index in 1:length(x)){
 print(index)
# [1] 1
# [1] 0
for (index in seq_along(x)){
 print(index)
```

Loops & Iteration - Good practice

Programming advice

Don't grow, replace.

```
x <- letters
result1 <- numeric()  # grow
result2 <- numeric(length(x)) # replace
for (index in seq_along(x)){
  result1 <- c(result1, paste(index, x[index])) # grow
  result2[index] <- paste(index, x[index]) # replace
}</pre>
```

Loops & Iteration - Functionals

A functional is a function that takes another function as an argument.

Focus on the apply-family. These functions apply a function repeatedly.

Can be seen as an abstraction of a for loop, with the following advantages

- requires less code to write
- does not store intermediate results
- no need to replace / grow

Functionals

The most commonly used functionals are:

- ullet lapply vector / list ightarrow list
- ullet sapply vector / list o vector (matrix)
- ullet apply matrix / array / data.frame o vector (matrix)
- tapply, by, aggregate
- mapply, Map
- rapply, eapply, vapply

All of which have an argument that should be a function.

lapply

Data frames are lists

```
lapply(iris, FUN = class)
# $Sepal.Length
# [1] "numeric"
# $Sepal.Width
# [1] "numeric"
#
# $Petal.Length
  [1] "numeric"
#
# $Petal.Width
# [1] "numeric"
#
# $Species
# [1] "factor"
```

lapply

- any type of element can be used
- other arguments can be passed through
- an annonymous function can be used

```
lapply(airquality, FUN = mean, rm.na = TRUE)
# $0zone
# [1] NA
# $Solar.R
# [1] NA
# $Wind
# [1] 9.957516
# $Temp
# [1] 77.88235
```

sapply

- wrapper around lapply
- if possible, the ouput is combined into a atomic vector or matrix

```
sapply(airquality, FUN = sd)
    Ozone Solar.R Wind Temp Month
                                              Day
              NA 3.523001 9.465270 1.416522 8.864520
#
       NA
sapply(airquality, FUN = quantile, prob = c(.1, .9),
      na.rm = TRUE)
#
     Ozone Solar.R Wind Temp Month Day
# 10% 11 47.5 5.82 64.2 5 4
# 90% 87 288.5 14.90 90.0 9 28
```

- for objects with dimension (matrix, array, data.frame)
- apply over (a) chosen dimension(s)

```
my_matrix <- matrix(1:6, nrow = 2)
apply(my_matrix, 1, max)  # apply per row

# [1] 5 6
apply(my_matrix, 2, max)  # apply per column

# [1] 2 4 6</pre>
```

Functions I

Building Blocks

Functions are the building blocks of R code. As frequent users of functions we know that they should:

- have a clear purpose
- be well documented
- be portable

Stepping Stone

Central stepping stone for R users:

Move from solely using functions written by others to writing your own functions.

Reasons

Why write functions?

- Readability
 - Shortens the code
 - Removes distractions, like references in a paper
 - Avoids repetition (DRY)
 - Easier understanding
- Transferability
 - Other use cases
 - Other projects
 - Other persons

Readability

```
Writing a function:
```

```
mean(mtcars$mpg)
```

[1] 20.09062

Not writing a function:

```
sum(mtcars$mpg)/dim(mtcars)[1]
```

[1] 20.09062

Readability

Writing a function:

```
# Min. 1st Qu. Median Mean 3rd Qu. Max.
# 10.40 15.43 19.20 20.09 22.80 33.90
```

Readability

Not writing a function:

```
round(c("Min." = min(mtcars$mpg),
   "1st Qu." = as.numeric(quantile(mtcars$mpg)[2]),
   "Median" = median(mtcars$mpg),
   "Mean" = mean(mtcars$mpg),
   "3rd Qu." = as.numeric(quantile(mtcars$mpg)[4]),
   "Max." = max(mtcars$mpg)), 2)

# Min. 1st Qu. Median Mean 3rd Qu. Max.
# 10.40 15.43 19.20 20.09 22.80 33.90
```

Elements of a function

- Name
- Arguments/Formals (input)
- Body (what happens inside)
- Output

Function definition

```
countNA <- function(x) {  # Name, Arguments/Formals
  out <- sum(is.na(x))  # Body
  out  # Output
}</pre>
```

Function Names

Every function needs a (meaningful) name!

- Usually a verb (what does the function do?)
- Avoid existing names
- Better longer than unclear
- CamelCase vs Snake_Case

Arguments

Most functions take one or multiple inputs. These are usually:

- One or two data arguments
- Additional Options

Programming advice

The less arguments, the better!

Output

Functions usually return a single object, namely the last evaluated object.

```
add_things_standard <- function(x = 1) {
  x2 <- x*2
  out <- x + x2
  out
}
add_things_standard(2)</pre>
```
